Question 1:

In any modern Operating System (OS), there are strong mechanisms for process isolation.

- The stack and heap of your application are stored in its own process memory space.
- Each process has its own virtual address space, so another application cannot access your stack or heap directly.
- The OS enforces memory protection (protected pages + read/write/execute permissions) to prevent unauthorized access to another process's memory.
- .NET applications run inside the Common Language Runtime (CLR) which manages memory and also isolates applications.

Thus, in general, you cannot access another application's stack or heap unless there is deliberate shared memory, debugging privileges, or injection techniques (like DLL injection).

Question 2

Delete a single student by ID:

```
int studentId = 5;
var student = await _context.Students.FindAsync(studentId);
if (student != null)
{
    _context.Students.Remove(student);
    await _context.SaveChangesAsync();
}
```

Delete all students:

```
var allStudents = _context.Students.ToList();
_context.Students.RemoveRange(allStudents);
await _context.SaveChangesAsync();
```

(Or on EF Core 7+)

```
await _context.Students.ExecuteDeleteAsync();
```
